Enthalpy Problems And Answers

Enthalpy problems and answers are fundamental topics in thermodynamics that frequently challenge students and professionals alike. Understanding how to approach and solve these problems is essential for mastering concepts related to energy transfer, phase changes, and chemical reactions. Whether you're studying for exams, working on research projects, or simply seeking to deepen your grasp of thermodynamic principles, being able to effectively analyze enthalpy problems will significantly enhance your proficiency. This comprehensive guide aims to clarify common types of enthalpy problems, demonstrate step-by-step solutions, and provide useful tips and resources to improve your problem-solving skills.

Understanding Enthalpy: The Foundation of Thermodynamics Problems

Before diving into specific problems and solutions, it is important to understand what enthalpy represents and how it fits into thermodynamic analysis.

What is Enthalpy?

Enthalpy (H) is a thermodynamic property defined as:

$$- H = U + PV,$$

where:

- U is the internal energy,
- P is the pressure,
- V is the volume.

It reflects the total heat content of a system at constant pressure and is a useful measure when analyzing processes involving heat transfer, especially in chemical reactions and phase changes.

Importance in Thermodynamics

Enthalpy is particularly useful because:

- Many processes occur at constant pressure, making ΔH (change in enthalpy) directly related to heat transfer.
- It simplifies the analysis of energy changes during phase transitions and chemical reactions.
- It allows for easier tabulation and use of standard data tables for various substances.

Common Types of Enthalpy Problems

Enthalpy problems can vary significantly depending on the context. Some typical categories include:

- Calculating the enthalpy change during phase transitions.
- Determining the heat absorbed or released in chemical reactions.
- Analyzing thermodynamic cycles (e.g., Rankine cycle, refrigeration cycle).

- Using enthalpy tables and diagrams to find specific values.
- Applying Hess's law for enthalpy calculations of complex reactions.

Each type requires different approaches and understanding of thermodynamic principles.

Approach to Solving Enthalpy Problems

Effective problem solving hinges on a systematic approach:

Step 1: Understand the Problem

- Identify what is being asked.
- Note the initial and final states of the system.
- Recognize if phase change, chemical reaction, or other processes are involved.

Step 2: Gather Data

- Extract known values such as temperature, pressure, mass, and specific enthalpy.
- Consult thermodynamic tables, charts, or diagrams as needed.

Step 3: Choose the Appropriate Method

- Use enthalpy tables for phase changes.
- Apply calorimetry equations for heat transfer.
- Use Hess's law for reactions involving multiple steps.

Step 4: Perform Calculations

- Calculate the change in enthalpy (ΔH).
- Ensure units are consistent.
- Pay attention to the sign convention: $\Delta H > 0$ for endothermic processes, $\Delta H < 0$ for exothermic processes.

Step 5: Verify and Interpret Results

- Check if the answer makes physical sense.
- Cross-verify with alternative methods if possible.

Sample Enthalpy Problems and Detailed Solutions

Below are some common problems with step-by-step solutions to illustrate the problem-solving process.

Problem 1: Enthalpy Change During Vaporization

Question:

A 2 kg sample of water is heated from 25°C to 100°C at atmospheric pressure. Determine the amount of heat absorbed during this process. Assume the specific heat capacity of water is 4.18 kJ/kg·°C.

Solution:

Step 1: Identify known data:

- Mass, $m = 2 \text{ kg}$
- Initial temperature, $T_i = 25^\circ\text{C}$
- Final temperature, $T_f = 100^\circ\text{C}$
- Specific heat capacity, $c_p = 4.18 \text{ kJ/kg}\cdot^\circ\text{C}$

Step 2: Calculate temperature change:

$$\Delta T = T_f - T_i = 100^\circ\text{C} - 25^\circ\text{C} = 75^\circ\text{C}$$

Step 3: Use heat transfer formula:

$$Q = m c_p \Delta T$$

Step 4: Compute:

$$Q = 2 \text{ kg} \cdot 4.18 \text{ kJ/kg}\cdot^\circ\text{C} \cdot 75^\circ\text{C}$$

$$Q = 2 \cdot 4.18 \cdot 75 = 627 \text{ kJ}$$

Answer:

The water absorbs approximately 627 kJ of heat to warm from 25°C to 100°C.

Problem 2: Enthalpy of Vaporization from Data Tables

Question:

Calculate the enthalpy change when 1 mol of water vaporizes at its boiling point (100°C) under 1 atm pressure. Given that the molar enthalpy of vaporization of water at 100°C is approximately 40.7 kJ/mol.

Solution:

Step 1: Recognize data:

- Moles of water, $n = 1 \text{ mol}$
- Enthalpy of vaporization, $\Delta H_{\text{vap}} = 40.7 \text{ kJ/mol}$

Step 2: Calculate total enthalpy change:

$$\Delta H = n \Delta H_{\text{vap}} = 1 \text{ mol } 40.7 \text{ kJ/mol} = 40.7 \text{ kJ}$$

Answer:

The enthalpy change for vaporizing 1 mol of water at 100°C and 1 atm is 40.7 kJ.

Problem 3: Using Hess's Law to Find Enthalpy Change

Question:

The following reactions are given:

- $\text{C} + \text{O}_2 \rightarrow \text{CO}_2$, $\Delta H^\circ = -393.5 \text{ kJ}$
- $\text{C} + \frac{1}{2}\text{O}_2 \rightarrow \text{CO}$, $\Delta H^\circ = -110.5 \text{ kJ}$

Calculate the enthalpy change for the reaction:

Solution:

Step 1: Recognize the target reaction and known reactions.

Step 2: Use Hess's law:

- To get $C + O \rightarrow CO$, subtract reaction 2 from reaction 1:

$CO \rightarrow CO + \frac{1}{2}O$ (reverse of reaction 2)

$\Delta H = -\Delta H = +110.5 \text{ kJ}$

- Add this to reaction 1:

$C + O \rightarrow CO$ ($\Delta H = -393.5 \text{ kJ}$)

$C + O \rightarrow CO$ (unknown)

Step 3: Set up the combination:

$(C + O \rightarrow CO) + (CO \rightarrow CO + \frac{1}{2}O)$

The net reaction:

$C + O \rightarrow CO + \frac{1}{2}O$

Step 4: Simplify:

$C + \frac{1}{2}O \rightarrow CO$

Step 5: Calculate total ΔH :

$\Delta H = \Delta H + (+110.5 \text{ kJ}) = -393.5 + 110.5 = -283 \text{ kJ}$

Answer:

The enthalpy change for $C + \frac{1}{2}O \rightarrow CO$ is -283 kJ .

Using Enthalpy Tables and Diagrams

Enthalpy tables are invaluable tools for solving real-world thermodynamic problems. They provide specific enthalpy values of substances at various temperatures and pressures.

Interpreting Enthalpy Tables

- Find the substance and phase (solid, liquid, vapor).
- Locate the temperature and pressure of interest.
- Read off the specific enthalpy (kJ/kg).

Example: Calculating Enthalpy Change in a Phase Change

Suppose you need to find the enthalpy change when 1 kg of water vapor condenses at 100°C and 1 atm:

- Use the specific enthalpy of saturated vapor at 100°C, approximately 2676 kJ/kg.
- The specific enthalpy of saturated liquid water at 100°C is approximately 419 kJ/kg.

Calculation:

$$\Delta H = h_{\text{vapor}} - h_{\text{liquid}} = 2676 - 419 = 2257 \text{ kJ}$$

Interpretation:

- The condensation releases approximately 2257 kJ of heat per kg of water.

Tips for Mastering Enthalpy Problems

- Familiarize with Tables and Charts: Regular practice with thermodynamic data tables and diagrams enhances speed and accuracy.
- Understand Sign Conventions: Remember that positive ΔH indicates heat absorbed (endothermic), negative ΔH indicates heat released (exothermic).
- Use Appropriate Units: Keep units consistent throughout calculations.
- Apply Conservation Laws: Use Hess's law and other thermodynamic principles to simplify complex problems.
- Practice Diverse Problems: Work through various problem types to build confidence and versatility.
- Verify Results: Always check if your answers make physical sense in terms of energy flow and process direction.

Enthalpy Problems and Answers: A Comprehensive Guide to Understanding and Solving

Understanding enthalpy problems is fundamental for students and engineers working in thermodynamics, especially when analyzing energy transfer in thermal systems. These problems often involve calculating heat transfer, work done, or changes in the energy content of a system during physical or chemical processes. Mastering the concepts and problem-solving techniques related to enthalpy can significantly enhance your ability to analyze real-world thermal systems such as engines, refrigerators, turbines, and chemical reactors.

This detailed guide aims to walk you through the core principles, common problem types, solution strategies, and example problems with detailed answers to build your confidence and competence in tackling enthalpy-related questions.

Understanding Enthalpy: The Foundation

What is Enthalpy?

Enthalpy (denoted as H) is a thermodynamic property that represents the total heat content of a system at constant pressure. It combines the internal energy of the system with the work done by the system due to expansion or compression. Mathematically:

$$[H = U + PV]$$

Where:

- U is the internal energy,
- P is the pressure,
- V is the volume.

In practical applications, changes in enthalpy (ΔH) are more relevant than absolute values because they indicate the heat transfer during processes at constant pressure.

Importance of Enthalpy in Thermodynamics

- Energy transfer analysis: Calculating heat exchanged or work done during processes.
- Chemical reactions: Determining heat of reaction, heat of formation, and energy balances.
- Phase changes: Understanding latent heats during boiling, melting, or condensation.
- Engineering design: Designing turbines, compressors, heat exchangers, and refrigeration cycles.

Common Types of Enthalpy Problems

Understanding the typical problem formats will help you develop effective strategies:

- Enthalpy of water and steam: Using steam tables to find enthalpy values at various states.
- Change in enthalpy during processes: Calculating ΔH based on initial and final states.
- Flow processes: Steady-flow energy equations involving enthalpy.
- Chemical reactions: Enthalpy of reaction calculations using Hess's Law.
- Phase change problems: Using latent heats and enthalpy of vaporization.

Core Concepts and Equations for Solving Enthalpy Problems

To effectively approach enthalpy problems, familiarize yourself with the following key concepts and equations:

- Enthalpy Change (ΔH)

[

$$\Delta H = H_{\text{final}} - H_{\text{initial}}$$

]

For processes at constant pressure, this often corresponds to heat transfer.

- Steady-Flow Energy Equation

For a control volume where flow is steady:

[

$$\dot{Q} - \dot{W} = \dot{m} \left(h_2 + \frac{v_2^2}{2} + gz_2 - h_1 - \frac{v_1^2}{2} - gz_1 \right)$$

\]

Where:

- $\dot{Q}$: heat transfer rate into the system,
- $\dot{W}$: work done by the system,
- $\dot{m}$: mass flow rate,
- h : specific enthalpy,
- v : velocity,
- z : elevation.

- Specific Enthalpy (h)

Expressed as:

\[

$$h = u + Pv$$

\]

But often, for liquids and vapors, it is more practical to use tabulated values or approximations.

- Enthalpy of a Ideal Gas

\[

$$h = c_p T + \text{constant}$$

\]

Where:

- c_p : specific heat at constant pressure,
- T : temperature.

- Enthalpy in Phase Changes

During phase changes:

\[

$$\Delta H_{\text{phase}} = \text{latent heat}$$

\]

For example, during vaporization:

\[

$$h_{\text{gas}} = h_{\text{liquid}} + h_{\text{fg}}$$

\]

Using Steam Tables and Property Charts

Most enthalpy problems involving water or steam require referencing steam tables. These tables provide properties such as:

- Enthalpy of saturated water (h_f)
- Enthalpy of saturated vapor (h_g)
- Quality (x)
- Specific volume (v)
- Pressure and temperature at various states

Tips for using steam tables:

- Identify the initial and final states clearly.
- Use the correct table (saturated or superheated).
- For mixtures, use the quality to interpolate enthalpy:

\[

$$h = h_f + x (h_g - h_f)$$

\]

Step-by-Step Approach to Solving Enthalpy Problems

- Identify the problem type: Is it a steady-flow process, a phase change, or a chemical reaction?
- List known data: Temperatures, pressures, enthalpies, velocities, etc.
- Determine the process specifics:
 - Is it at constant pressure?
 - Is it involving phase change?
 - Are the flow rates known?
- Select appropriate property data:
 - Use steam tables, thermodynamic property charts, or equations.
- Apply relevant equations:
 - Use the first law of thermodynamics or other relevant equations.
- Calculate the unknowns:
 - Enthalpy changes, heat transfer, work, etc.
- Check units and reasoning:
 - Ensure consistency and physical plausibility.

Example Problems with Detailed Solutions

Example 1: Enthalpy Change During Heating of Water

Problem:

Calculate the change in enthalpy when 1 kg of water is heated from 20°C to 150°C at atmospheric pressure. Use specific heats $(c_p = 4.18 \text{ kJ/kg}\cdot\text{K})$.

Solution:

- Identify initial and final states:
 - Initial temperature, $(T_1 = 20^\circ\text{C})$
 - Final temperature, $(T_2 = 150^\circ\text{C})$
- Assuming constant specific heat:

$\{$

$$\Delta h = c_p (T_2 - T_1)$$

$\}$

- Calculate:

$\{$

$$\Delta h = 4.18 \times (150 - 20) = 4.18 \times 130 = 543.4 \text{ kJ}$$

$\}$

Answer: The enthalpy increases by approximately 543.4 kJ.

Example 2: Enthalpy of Vaporization Using Steam Tables

Problem:

Determine the enthalpy change when 1 kg of saturated water at 100°C vaporizes completely into steam at the same temperature.

Solution:

- Find the properties from steam tables:
- h_f at 100°C ? 419 kJ/kg (enthalpy of saturated liquid)
- h_g at 100°C ? 2676 kJ/kg (enthalpy of saturated vapor)
- Calculate the enthalpy of vaporization:

$\{$

$$\Delta H_{\text{vap}} = h_g - h_f = 2676 - 419 = 2257 \text{ kJ}$$

$\}$

- Total enthalpy change for 1 kg:

$\{$

$$\boxed{\Delta H = 2257 \text{ kJ}}$$

$\}$

Answer: Approximately 2257 kJ of energy is required for vaporization.

Example 3: Steady-Flow Energy Equation for a Turbine

Problem:

A steam turbine receives 2 kg/sec of saturated vapor at 3 MPa and 400°C , expanding isentropically to 0.1 MPa. Find the power output of the turbine.

Solution:

- Determine initial properties (state 1):

- From superheated steam tables at 3 MPa and 400°C:
- $(h_1 \approx 3213, \text{kJ/kg})$
- Determine final properties (state 2):
- At 0.1 MPa (saturated vapor):
- $(h_{\text{ MPa}} \approx 2676, \text{kJ/kg})$
- Assumption:
- Isentropic expansion, so entropy remains constant.
- Calculate work output:

$\backslash$

$$W = \dot{m} (h_1 - h_2) = 2 \times (3213 - 2676) = 2 \times 537 = 1074, \text{kJ}$$

$\backslash$

Answer: The turbine produces approximately 1074 kW of power.

Common Pitfalls and Tips for Accurate Solutions

- Always verify the state conditions: Ensure you are using the correct property data for saturated, superheated, or compressed states.
- Use consistent units: kJ, kPa, kg, °C, etc., and convert units if necessary.
- Check process assumptions: Is

Question What is enthalpy and how is it used in solving thermodynamics problems?

Answer Enthalpy is a thermodynamic property defined as $H = U + PV$, where U is internal energy, P is pressure, and V is volume. It is used to analyze energy changes in processes involving heat transfer and work, especially at constant pressure. In problems, enthalpy helps determine heat exchanged during reactions or phase changes by comparing initial and final states. How do you calculate the change in enthalpy for a chemical reaction? The change in enthalpy (ΔH) for a reaction can be

calculated using the formula: $\Delta H = \sum \Delta H_{\text{products}} - \sum \Delta H_{\text{reactants}}$. Alternatively, for reactions at constant pressure, you can use standard enthalpies of formation: $\Delta H = \sum n \times \Delta H_f(\text{products}) - \sum n \times \Delta H_f(\text{reactants})$, where n is the number of moles. What is the significance of Hess's Law in enthalpy problems? Hess's Law states that the total enthalpy change for a chemical reaction is the same regardless of the pathway taken, allowing us to calculate enthalpy changes for complex reactions by combining known reactions. It simplifies enthalpy calculations by enabling the use of tabulated data and multiple steps. How do phase changes affect enthalpy calculations? Phase changes involve latent heat, which is the enthalpy change associated with melting, vaporization, or sublimation. To calculate enthalpy during phase changes, use the known latent heat values (e.g., heat of vaporization) and multiply by the amount of substance undergoing the phase change, then add or subtract these values from other process enthalpies. What role does the heat capacity play in enthalpy problems involving temperature changes? Heat capacity (C) indicates how much heat is needed to change an object's temperature. When solving enthalpy problems involving temperature changes, ΔH can be calculated using $\Delta H = C \times \Delta T$, where ΔT is the temperature change. For varying heat capacities, integration over temperature may be required to find the total enthalpy change. How can enthalpy problems be approached when dealing with ideal gases? For ideal gases, enthalpy depends only on temperature, not pressure or volume. The change in enthalpy during a temperature change can be calculated using $\Delta H = n \times C_p \times \Delta T$, where C_p is the molar heat capacity at constant pressure. This simplifies calculations, especially when dealing with ideal gas processes.
