In this comprehensive guide, we will explore the core principles of nuclear decay, how to interpret decay problems, and tips on effectively utilizing an answer key to improve learning outcomes.

Understanding Nuclear Decay

Nuclear decay, also known as radioactive decay, is a spontaneous process by which unstable atomic nuclei release energy by emitting radiation. This transformation results in the formation of different elements or isotopes and is fundamental to many scientific and practical applications, including radiometric dating, nuclear medicine, and nuclear power.

Basics of Nuclear Decay

- Radioactive Isotopes (Radioisotopes): Unstable variants of elements with excess nuclear energy.
- Decay Modes: The ways in which nuclei change, primarily:
 - Alpha decay (?)
 - Beta decay (?)
 - Gamma decay (?)
- Decay Constant (?): The probability per unit time that a nucleus will decay.
- Half-life ($t_{1/2}$): The time taken for half of a sample of radioactive material to decay.

Decay Law and Equations

The fundamental equation governing nuclear decay is:

$$N(t) = N_0 e^{-\lambda t}$$

Where:

- $N(t)$ = number of remaining undecayed nuclei at time t

- (N_0) = initial number of nuclei
- (λ) = decay constant
- (t) = elapsed time

The relationship between half-life and decay constant is:

$$t_{1/2} = \frac{\ln 2}{\lambda}$$

Common Types of Nuclear Decay Problems and How to Solve Them

Using a nuclear decay answer key involves understanding typical problem types encountered in coursework and exams. Here are some common problem categories:

1. Calculating Remaining Nuclei After a Certain Time

Problem Example:

A sample contains 10,000 atoms of a radioactive isotope with a half-life of 5 hours. How many atoms remain after 20 hours?

Solution Steps:

- Determine the number of half-lives elapsed:

$$\text{Number of half-lives} = \frac{t}{t_{1/2}} = \frac{20}{5} = 4$$

- Use the half-life decay formula:

$$N = N_0 \left(\frac{1}{2}\right)^{\text{number of half-lives}}$$

- Calculate:

$$N = 10,000 \times \left(\frac{1}{2}\right)^4 = 10,000 \times \frac{1}{16} = 625$$

Answer: 625 atoms remain after 20 hours.

2. Determining the Decay Constant or Half-life

Problem Example:

If a radioactive isotope has a decay constant of 0.1386 per hour, what is its half-life?

Solution:

- Use the relation:

$$t_{1/2} = \frac{\ln 2}{\lambda}$$

- Calculate:

$$t_{1/2} = \frac{0.6931}{0.1386} \approx 5 \text{ hours}$$

Answer: The half-life is approximately 5 hours.

3. Finding the Time for a Certain Decay

Problem Example:

How long does it take for a sample to decay from 1000 atoms to 125 atoms if the half-life is 3 hours?

Solution:

- Determine the fraction remaining:

$$\frac{N}{N_0} = \frac{125}{1000} = 0.125$$

- Recognize that:

$$\frac{N}{N_0} = \left(\frac{1}{2}\right)^n$$

where n is the number of half-lives.

- Solve for n :

$$0.125 = \left(\frac{1}{2}\right)^n$$

$$n = \log_{1/2}(0.125) = \log_{1/2}(2^{-3}) = 3$$

- Calculate total time:

$$t = n \times t_{1/2} = 3 \times 3 = 9 \text{ hours}$$

Answer: It takes 9 hours for the sample to decay from 1000 to 125 atoms.
